

RD-1 — Funds Flow Document

Mintware · Bridge/Stripe Stablecoin-Issuing Card Program

Diagram

Narrative Walkthrough

1. Funding wallet.

Each card is funded from the member's own Privy embedded wallet — one wallet, one card. The member holds the wallet; Mintware never holds a private key that can move 100% of a member's balance unilaterally.

2. The allowance, not a balance transfer.

The funding wallet grants a capped ERC-20 approve(spender, allowance) on USDC to a per-program Bridge-provisioned spender address — a capped standing pull-right, sized to daily cap × coverage days, hard-ceilinged at \$50,000, further scoped to a multiple of the intended buffer target when configured. Bridge can never pull more than this capped amount, regardless of what else sits in the wallet.

3. At swipe time,

Bridge/Stripe pull the exact authorized amount via that allowance — reading the wallet's real on-chain USDC balance, never a vault NAV computation.

4. The authorization decision

runs belt-and-suspenders: a role-based daily spend cap checked against the member's actual approved spend for the day, plus an optional standing tier that can only ever widen a limit within the existing hard cap. Suspenders are a flat pre-funded buffer check or a live NAV-based hold via edge-auth, which fails closed if unconfigured.

5. Where the money sits.

The USDC the buffer draws from originates in the Mintware Treasury Vault — a senior/junior tranche structure. Community-facing senior capital is the par-protected, spendable claim; the team's own junior capital is contractually first-loss and is drawn down before senior capital in any shortfall — code-enforced, not discretionary.

6. Settlement

is executed by a designated oracle signer holding a specific on-chain role, not an arbitrary hot wallet.

Custody Characterization

Mintware's card program is non-custodial. The card funding wallet is the member's own Privy-embedded wallet — self-custodied, with no single Mintware-controlled key capable of moving it unilaterally. The underlying treasury position is likewise not held in a Mintware-controlled bank account: it is a smart-contract-governed pool, with depositor claims enforced by contract logic rather than by Mintware custody. Mintware at no point holds a private key or account that can unilaterally move user funds.
